# Studies in the genus Acacia (Mimosaceae)—5\* —Miscellaneous new phyllodinous species—

By B. R. Maslin

#### **Abstract**

Four new, endemic, Western Australian Acacia species are described: A. anfractuosa sp. nov., A. argutifolia sp. nov., A. jacksonioides sp. nov. and A. simulans sp. nov. These species belong to Bentham's division Phyllodineae.

### 1. Acacia anfractuosa Maslin sp. nov.

Frutex vel arbor parva ad 4 m alta, diffusa, exilis; rami plerumque penduli, flexuosi, glabri vel strigosi. Stipulae caducae. Phyllodia linearia, ad 170(200) mm longa 1-2 mm lata, inter veniis minute strigosis, in sectione transversali rhombea (ubi angusta) ad + plana; costa nervisque marginalibus prominentibus; inter eos 1-3 nervi tenuiores. Glans obseura in margine supera phyllodii ad extremitatem distale pulvini. Pedunculis 5-7(10) mm longis; capitula globulosa ad leviter obloidea. Florae 5-merae. Legumen lineare, ad 120 mm longum, 1·5-2·5 mm latum. Semina in legumine longitudinalia, ellipsoidalia, 4·5-5 x 1·5 mm.

Type: 26 km E of Karalee on Great Eastern Highway, Western Australia, 15 December 1971, B. R. Maslin 2402 (holo; PERTH; iso: CANB, K, NY).

Diffuse, openly branched, rather spindly slirub or small tree to 4 m tall, either single-stemmed or dividing at groun ! level into ca. 3 main trunks; bark grey, smooth but sometimes slightly roughened at base of trunk; branches often pendulous, flexuous, terete, obscurely ribbed on branchlets, glabrous or strigose (hairs densest around base of phyllodes and between ribs on branchlets), light brown to red-brown, soon becoming grey. Stipules caducous. Young shoots resinous, densely strigose. Mature phyllodes linear, to 170(200) mm long, 1-2 mm wide, simply curved or sometimes ± sigmoid, spreading, slightly resinous, minutely strigose between vcins, olive-green to grey-green, rhombic in cross section (when narrow) to + flat; midrib and marginal nerves prominent broad and yellowish, 1-3 finer nerves occur between each midrib and marginal nerve; apex sometimes uncinate, not pungent, brown; pulvinus cylindrical, 0.5-1.5 mm long, obscurely transversely wrinkled, minutely strigose. Gland obscure, situated on upper margin of phyllode at distal end of pulvinus, lamina tissue insignificantly swollen around the gland. Inflorescences simple, often arising from base of a new shoot within axil of phyllode. 1-2(3) per node; peduncles 5-7(10) mm long, minutely strigose (hair density variable), basal bract caducous solitary ovate and minute (ca. 0.5 mm long); receptacle obloid, 1.5-3 mm long, densely puberulous to glabrescent; flower lieads bright yellow, globular to obloid, 7-8 mm long at anthesis, with  $22-32 \pm loosely$  arranged flowers. Bracteoles 0.7-0.9 mm long, puberulous abaxially, claws linear, laminae ovate and inflexed. Flowers 5-merous;  $calyx \nmid to ca. \nmid length$  of corolla, divided for { its length into oblong obtuse ciliolate lobes, tube brown sparsely to densely puberulous and nerveless: petals ca. 2 mm long, connate for  $\frac{1}{3} - \frac{1}{2}$  their length, glabrous, obscurely 1-nerved. Legimes linear, to 120 mm long, 1.5-2.5 mm wide, firmly chartaceous, slightly raised over seeds, obscurely longitudinally nerved, minutely silvery-strigose (hairs dense on young legumes), dark brown; margins somewhat contracted between seeds (indentations shallowly concave), marginal nerve scarcely thickened broad glabrous and yellowish. Seeds longitudinal in legume, ellipsoid, 4·5-5 mm long, 1·5 mm wide, brown with cream-coloured mottlings, a dark brown line extends around periphery of seed, somewhat shiny; pleurogram horseshoe-shaped, open towards the hilum, obscure; areole 0.5 mm long; funicle slender and convoluted, gradually thickened into a pileiform, whitish aril.

<sup>\*</sup> The previous four papers in this series were published in Nuytsia vol. 1, nos. 3, 4 and 5.

Distribution: (Figure 1) Western Australia: Bruce Rock to near Kellerberrin then east to Boorabbin (about halfway between Southern Cross and Coolgardie).

Habitat: Yellow sand in sandplain heath.

WESTERN AUSTRALIA; 283 mi peg on Great Eastern Highway (454 km E of Perth), T. E. H. Aplin 1953 (L, PERTH, RSA); Bruee Rock, E. T. Bailey s.n., Sept. 1933 (PERTH); 5 mi (8 km) north of Muntadgin, E. T. Bailey 284 (MEL, PERTH); Near Southern Cross, W. E. Blackall s.n., Sept. 1929 (CANB, PERTH); Near Kellerberrin, G. E. Brockway s.n., Dec. 1943 (PERTH); 1 mi (1.6 km) E of Boorabbin, C. A. Gardner 7998 (K, PERTH); About 5.5 mi (10.5 km) E of Muntadgin, B. R. Maslin 1822 (AD, B, BRI, MEL, NSW, PERTH).

Flowering and fruiting period: The flowering season begins in July-August and extends to at least December. Legumes are initiated from October to at least December; mature seed has been collected in December. The previous year's legumes are often present on the bushes during the next flowering season and these sometimes contain a few ripe seed.

Because the flower heads of A. anfractuosa vary from globular to obloid, it is difficult to fit this species into Bentham's classification (1864). The taxon is most closely allied to A. heteroneura Meisn. (Plurinerves-Nervosae, according

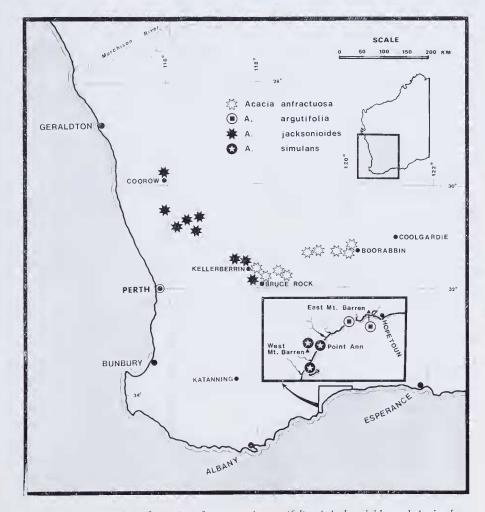

Figure 1. Distribution of Acacia anfractuosa, A. argutifolia, A. jacksonioides and A. simulans,

to Bentham, I.c.) and A. jutsonii Maiden (Juliflorae-Stenophyllae, according to Maiden, 1917) but it differs from both in its often pendulous, flexuose branches, and its curved phyllodes.

Mainly because of its flexuose, often pendulous branches and its long, narrow phyllodes and legumes, A. anfractuosa has in the past often been referred to as A. hynesiana W. V. Fitzg. This latter name is probably a synonym of A. merinthophora E. Pritzel but further work is needed to confirm this. Acacia anfractuosa differs significantly from the types of both A. hynesiana (W. V. Fitzgerald s.n.—MEL, NSW, PERTH) and A. merinthophora (L. Diels 2858—PERTH; E. Pritzel 316—NSW) in the following characters: phyllodes differently veined, flower heads pedunculate, and flowers 5-merous.

Between Mukinbudin and Welbungin (about 80 km north of Merrcdin) there occurs a variant of A. anfractuosa which differs from the typical form in that its phyllodes are terete and have four, equally spaced, very prominent, longitudinal grooves running the entire length of the phyllode. This variant is known from only two collections, viz. W. E. Blackall 848 and C. A. Gardner 2754, both of which are in flower. Judging from the herbarium label information, this variant has the same distinctive habit as the typical form. Further information is needed concerning this variant before its taxonomic status can be determined.

The specific epithet refers to the characteristic prominently flexuose branches.

### 2. Acacia argutifolia Maslin sp. nov.

Frutex ad 0.5 m altus; ramuli inconspicue nervati, modice puberuli (rami parce puberuli). Stipulae ± persistentes. Phyllodia aggregata, non verticillata, lineari-trigona, 6–13 x 1 mm, glabra, pungentia. Glans inconspicua, interdum nulla. Capitula globulosa. Florae 4-merae (petalae raro 5); calycis tubus glabratus; petala glabra, enervia.

Type: Northern slopes of Whoogarup Range, about 29 km due W of Hopetoun, Western Australia, 8 Oct. 1975, B. R. Maslin 3886 (holo: PERTH; iso: CANB, K, MEL, NY).

Low, spreading, intricate shrub 0.2-0.5 m tall and 1.2-1.7 m diam. dividing near ground level into 3-4 main branches; bark light grey on branches, red towards ends of branchlets; lenticels fairly conspicuous; branchlets terete. very obscurely nerved, moderately puberulous (hairs sparser on branches). Stipules very narrowly triangular, 1.5-2 mm long, somewhat persistent. Phyllodes scattered (not verticillate) and crowded, linear-trigonous (midrib prominent below but normally absent above, lateral angles conspicuous), 6-13 mm long, ca. 1 mm wide, ascending to almost patent, slightly curved, quite rigid, glabrous, bright to medium green, stomata numerous (quite apparent at x 10 mag.), pungent (mucrone 1 mm long, straight, brown or yellow); pulvims ca. 0.5 mm long, somewhat dilated towards the base. Gland inconspicuous, sometimes absent, situated on upper surface of phyllode at, or near, distal end of pulvinus. Inflorescences simple, 1 per node; peduncles 5 mm long, glabrous, basal bract solitary and triangular: receptacle obloid, glabrous; flower heads globular, pale yellow, with 23-25 flowers. *Bracteoles* almost 1 mm long, glabrous, claws oblong, laminae ovate and acute. Flowers 4-merous (in some heads a few flowers with 5 petals occur); calyx ca. ½ length of petals, divided for  $\frac{1}{2}-\frac{2}{3}$  its length into oblong minutely ciliolate lobes, tube glabrescent; petals ca. 1.2 mm long, connate for ½ their length, glabrous, nerveless; ovary sessile, sparsely hairy. Legumes narrowly oblong, to 40 mm long, 2-4 mm wide, somewhat chartaceous, slightly raised over seeds, slightly curved, glabrous to glabrescent, tan to grey-brown, narrowed at both ends, stipe 3 mm long; margins slightly contracted between seeds, barely thickened, yellow. Seeds longitudinal in legume, obloid to ellipsoid, ca. 3 mm long and 1.8 mm wide, brown, with a darker brown line extending around periphery of seed, dull; pleurogram quite obvious, open towards the hilum; areole ca. 2.5 x 0.7 mm; funicle filiform, abruptly expanded into a conical (although often compressed at apex), white aril.

Distribution: (Figure 1) South-west Western Australia: known only from near East Mount Barren and Quoin Head (K. Newbey, pers. comm.), about 10–30 km west of Hopetoun.

Habitat: Grows in shallow sand over quartzite in low open heath.

WESTERN AUSTRALIA: East Mount Barren, south of Ravensthorpe, C. A. Gardner and W. E. Blackall 1428 (PERTH); East Mount Barren, K. Newbey 1618 (G, NSW, PERTH).

Flowering and fruiting period: Flowers intermittently from late July to January (K. Newbey, pers. comm.). Legumes containing mature seeds have been collected in early October. These were present on bushes that were just beginning their flowering period.

Using Bentham's classification (1864) A. argutifolia occurs in the Pungentes-Uninerves but it is not closely related to the other members of this group. This species is most closely allied to A. simulans Maslin from which it is readily distinguished by its scattered (not verticillate) phyllodes—see p. 101 below for a full discussion on these two species.

The specific epithet refers to the characteristic sharp-pointed phyllodes.

#### 3. Acacia jacksonioides Maslin sp. nov.

Frutex 0.3-0.6 m altus, densus, intricatus, divaricate-ramosus, ramulis brevibus spinescentibus; rami nervati, glabri. Stipulae caducae. Phyllodia leviter et oblique ovata ad oblonga vel elliptica,  $3.5-8(10) \times 2.5-4(5)$  mm, glabra, marginibus  $\pm$  undulatis, costis prominentibus. Pedunculi 3-6 mm longi, glabri; capitula globosa. Bracteolae nullae. Florae 5-merae Legumen anguste oblongum, plerumque 25-30 mm longum, 3 mm latum. Sentina in legumine longitudinalia, obloidea,  $2-2.5 \times 1.2-1.7$  mm.

Type: Nalyaring Well, 20 km N of Kellerberrin towards Yelbeni, Western Australia, 16 July 1970, B. R. Maslin 592 (holo: PERTH; iso: CANB, K, NY).

Dense, intricate, divaricately branched, rounded slurub 0.3-0.6 m tall, with short, spinescent branchlets; branches slightly flexuose, terete, quite prominently ribbed (ribs yellow), glabrous, glaucous (when fresh). Stipules caducous. Phyllodes slightly obliquely ovate to oblong or elliptic, 3:5-8(10) mm long, 2.5-4(5) mm wide, patent or somewhat reflexed, glabrous, margins slightly thickened and normally \(\preceq\) undulate, midrib prominent, lateral veins very obscure, apiculum short somewhat sharp and dark brown; pulvinus ca. 0.5 mm long, obscurely wrinkled. Gland not prominent, situated on upper margin of phyllode 1-2 mm above the pulvinus. Inflorescence an extremely reduced raceme consisting of a single flower head, 1(2) per node: raceme axis minute (0.1 mm long); peduncles 3-6 mm long, glabrous, subtended by 2 basal bracts: flower heads globular, yellow, with 10-14 flowers. Bracteoles absent. Flowers 5-merous; calyx \frac{1}{3} to slightly less than \frac{1}{2} length of corolla, divided for \frac{1}{1} it; length into obtuse glabrous or ciliolate lobes, tube nerveless and glabrous or glabrescent: petals 1.5-2 mm long, connate for ca. 1/3 their length but readily separating, very obscurely 1-nerved, glabrous; ovary glabrous. Legumes narrowly oblong, mostly 25-30 mm long. 3 mm wide, firmly chartaceous, curved, slightly undulate, quite prominently raised over seeds (but bulged on one surface of legume only—opposite surfaces for adjacent seeds), glabrous, brown; marginal rib narrow, slightly contracted between seeds, pale coloured. Seeds longitudinal in legume, obloid, 2-2.5 mm long, 1 2-1.7 mm wide, brown. shiny; pleurogram horseshoe-shaped, open towards the hilum; areole 0.7 mm long; funicle filiform, abruptly expanded into a thickened, curved, pale yellow aril.

Distribution: (Figure 1) Western Australia: wheatbelt region from near Coorow south-east to near Bruce Rock.

Habitat: Gravelly sand or loam commonly on hilltops.

WESTERN AUSTRALIA: About 8 mi (12 · 9 km) N of Coorow, C. Chapman s.n., 1 July 1973 (PERTH); Yorkrakine, C. A. Gardner 8044 (BRI, MEL, PERTH, RSA); Ballidu, R. T. Lange 56 (PERTH); About 29 km due NW of Bruce Rock, B. R. Maslin 2364 (PERTH); About 37 km S of Moora towards Perth, B. R. Maslin 3275 (NSW, PERTH).

Flowering and fruiting period: Flowers in July and August; a few undehisced legumes remain on the bushes to mid-December.

According to Bentham's classification (1864) A. jacksonioides occurs in the Uninerves-Spinescentes. At PERTH this species has previously been known as A. intricata S. Moore. However, it is not closely related to this species. Acacia jacksonioides is distinguished from A. intricata by its short, divaricate, spinescent branchlets, its larger, undulate, less rigid phyllodes, and its longer peduncles.

The short, divaricate, spinescent branchlets, and relatively small phyllodes and flower heads render this new species similar to A. erinacea Benth. However, A. jacksonioides is readily recognized by its differently shaped, normally somewhat undulate, more prominently nerved phyllodes, its much narrower legumes, and its longitudinally arranged seeds. In its phyllode morphology, A. jacksonioides is similar to A. semicircinalis Maiden and Blakely (Uninerves-Brevifoliae) but differs from this species in its divaricate, spinescent branchlets, and its smaller flower heads.

The specific epithet alludes to the general similarity in branching pattern between the new species and some members of the genus *Jacksonia* e.g. *J. hakeoides* Meisn. and *J. spinosa* (Labill.) R.Br.

#### 4. Acacia simulans Maslin sp. nov.

Frutex diffusus ad 1 m altus; ramuli teretes, glabri vel sparsim antrorse strigosi. Stipulae ca. 1 mm longae. Phyllodia verticillata 6-9-na, lineari-tetragona, 8-12 mm longa, patentia ad leviter reflexa, pungentia. Glans inconspicua. Capitula globulosa ad leviter obloidea. Florae 4-merae. Legumen  $\pm$  moniliforme, ad 70 mm longum, ad 4 mm latum. Semina in legumine longitudinalia, obloidea, ca. 4 mm longa, 2·5-3 mm lata, brunnea.

Type: About 1.6 km due NW of Mount Bland, Fitzgerald River National Park, Western Australia, 30 August 1973, B. R. Maslin 3483 (holo: PERTH; iso: BRI, CANB, K, MEL, NY, PERTH).

Diffuse, openly branched shrub to 1 m tall, dividing at ground level into a number of slender spreading branches; bark smooth, grey on branches, brown on branchlets; lenticels often quite prominent; branchlets terete, very obscurely nerved, glabrous or sparsely antrorsely strigose. Stipules narrowly triangular, ca. 1 mm long. Phyllodes regularly verticillate, 6-9 per whorl, linear-tetragonous (sometimes appearing trigonous due to reduction of midrib on upper surface of phyllode), 8-12 mm long, patent to slightly reflexed, straight or slightly curved, quite rigid, glabrous or sometimes glabrescent, stomata numerous (quite apparent at x 10 mag.), pungent (mucrone 1 mm long, straight, brown); pulvinus ca. 0.5 mm long, slightly dilated towards the base. Gland inconspicuous, situated on rib on upper surface of phyllode 2-4 mm above the pulvinus, orifice circular to oblong and 0·1-0·2 mm diam. Inflorescences simple, 1-2(3) per node: peduncles 2-4(5) mm long, glabrous, basal bract solitary; receptacle obloid, glabrous; flower heads light yellow, globular to slightly obloid, with 16-20 flowers. Bracteoles ca. I min long, puberulous abaxially, laminac ovate. Flowers 4-merous:  $calyx = -\frac{1}{8}$  length of petals, divided for 1-1 its length into broadly triangular slightly keeled and inflexed lobes, tube puberulous; petals ca. 1.5 mm long, free to base, glabrous, nerveless; ovary minutely stipitate, glabrous or papillosc. Legumes + moniliform, to 70 mm long, to 4 mm wide, firmly chartaceous, slightly curved, glabrous, brown, stipe ca. 6 mm long; marginal nerve narrow and yellow. Seeds longitudinal in legume, obloid to elliptic, ca. 4 mm long, 2·5-3 mm wide, dark

brown, slightly shiny; pleurogram quite prominent, open towards the hilum; areole 3 mm long, 1.5 mm wide; funicle slender, reflexed below a thickened, conical, white aril.

Distribution: (Figure 1) South-west Western Australia: known only from a restricted area along the south coast in the vicinity of West Mount Barren (about 70 km due WSW of Hopetoun).

Habitat: Sand among the low shrub stratum of Eucalyptus tetragona (R.Br.) F. Muell, tall open shrubland.

WESTERN AUSTRALIA: Below Mount Bland, near West Mount Barren, ESE of Ongerup, T. E. H. Aplin, I. Lethbridge and R. Coveny 3317 (PERTH); Near Point Ann, A. S. George 10044 (AD, PERTH); About 1:6 km due NW of Mount Bland, Fitzgerald River National Park, B. R. Maslin 3482 (B. BRI, K, L, MEL, NSW, PERTH, RSA); 1 mi (1:6 km) NW of Mount Maxwell, K. Newbey 827.

Flowering and fruiting period: Flowers from July to September; seeds mature in the first two weeks of December.

Using Bentham's classification (1864) A. sinulans occurs in the series Brunioideae, however, it is not closely related to the other members of this group. Acacia sinulans has its closest affinities with A. argutifolia Maslin (see p. 98 above) which occurs in the Pungentes-Uninerves. These two species have the same basic phyllode and legume structure and very similar inflorescences. Acacia sinulans is distinguished from A. argutifolia by its verticillate phyllodes and its less hairy branchlets. Neither species shows a close relationship with previously described Western Australian acacias.

In his discussion under *A. cedroides* Benth., Pedley (1972, p. 12) referred to a possible new species collected from near Mount Maxwell (*K. Newbey* 827); this species is *A. simulans*. As both *A. cedroides* and *A. simulans* have pungent and verticillate phyllodes they superficially resemble one another, but they are not particularly closely related. In addition to the characters mentioned by Pedley, *A. simulans* differs from *A. cedroides* in its habit (more diffuse), its normally shorter and more spreading phyllodes, its 4-merous flowers, its \_\_ moniliform, firmly chartaceous, non-striate legumes, and its darker coloured seeds.

Pedley (l.c.) noted that A. cedroides was not closely related to the other regularly verticillate members of the Brunioideae. From my own observations it appears as though this species has its closest affinities with A. laricina Meisn. a member of the Pungentes-Uninerves. Both taxa share similar phyllode, inflorescence and legume characters. The main difference between them is their phyllode arrangement (verticillate in the former taxon, scattered and crowded in the latter). An interesting comparison can be made between this pair of species and the A. sinulans-A. argutifolia pair. Both A. cedroides and A. simulans have regularly verticillate phyllodes and therefore, according to Bentham's classification, occur in the Brunioideae, but they are anomalous members of this group. Likewise, A. laricina and A. argutifolia (the respective closest relative of the above two species) are atypical members of Bentham's Pungentes-Uninerves: both these taxa have scattered (not verticillate) and crowded phyllodes. These two species-pairs undoubtedly constitute natural From the above it is seen that parallel evolution has taxonomic groups. occurred in these two unrelated groups of species. Thus while Bentham's classification of Acacia is undoubtedly useful for grouping species of this vast genus, it does not necessarily reflect the true relationships of the taxa contained

The specific epithet refers to the superficial resemblance of the new species to A. cedroides.

## Acknowledgments

The author wishes to express his appreciation of the assistance given by Mr. Ken Newbey for his valuable comments on A. argutifolia and A. simulans. Mr. Alex George is also gratefully acknowledged for checking the latin descriptions.
